## Properties of ROC

#### Properties of ROC

• <u>Property #1</u>: The ROC is a ring or disk in the z-plane center at origin.

- <u>Property #2</u>: The Fourier transform of x|n| converges absolutely if and only if the ROC of the z-transform includes the unit circle.
- <u>Property #3</u>: The ROC contains no poles.
- <u>Property #4</u>: If x|n| is a finite impulse response (FIR), then the ROC is the entire z-plane.
- <u>Property #5</u>: If x|n| is a right-sided sequence then the ROC extends outwards from the outermost finite pole to infinity.
- <u>Property #6</u>: If x|n| is left sided then the ROC extends inward from the innermost nonzero pole to z=0.

#### Properties of ROC (cont.)

<u>Property #7</u>: If X(z) is rational, i.e., X(z)=A(z) / B(z) where A(z) and B(z) are polynomials, and if x[n] is right-sided, then the ROC is the region outside the outermost pole.

## Inverse Z-transform

#### Inverse Z-Transform

- The inverse z-transform is used to derive x[n] from X(z).
- There are different methods with which we can derive x[n] if X(z) is given.
- By considering r fixed, inverse of z-transform can be obtained from inverse of Fourier transform. That is :

$$X(re^{j\omega}) = F\left\{x[n]r^{-n}\right\}$$

For any value of r so that z=re<sup>jω</sup> is inside the ROC.
Applying the inverse Fourier transform to both sides of above equation yields:

## Inverse Z-Transform (cont.) $x[n]r^{-n} = F^{-1}\{X(re^{j\omega})\}$ or $x[n] = r^n F^{-1}\{X(re^{j\omega})\}$

 Using the inverse Fourier transform expression in above equation we have:

$$x[n] = r^{n} \frac{1}{2\pi} \int_{2\pi} X(re^{j\omega}) e^{j\omega n} d\omega$$

 Or moving the exponential factor r<sup>n</sup> inside the integral and combining it with the term e<sup>jωn</sup>:

$$x[n] = \frac{1}{2\pi} \int_{2\pi} X(re^{j\omega}) (re^{j\omega})^n d\omega$$

#### Inverse Z-Transform (cont.)

 That is we can recover x[n] from its z-transform evaluated along a contour z=re<sup>jω</sup> in the ROC with r fixed and ω varying over a 2π interval.

 Consequently in terms of an integration in the z-plane above equation becomes:

$$x[n] = \frac{1}{2\pi j} \oint X(z) z^{n-1} dz$$

Methods to obtain Inverse Z-transform:
 If X(z) is rational, we can use expanding the rational algebraic into a linear combination of lower order terms and then one may use:

• If ROC is out of pole  $z = a_i$ :

$$X(z) = \frac{A_i}{1 - a_i z^{-1}} \rightarrow x[n] = A_i a_i u[n]$$

#### Inverse Z-Transform (cont.)

If ROC is inside of  $z = a_i$ :

$$X(z) = \frac{A_i}{1 - a_i z^{-1}} \rightarrow x[n] = -A_i a_i u[-n - 1]$$

• Do not forget to consider ROC in obtaining inverse of ZT. If X(z) is non-rational, use Power series expansion of X(z), then apply  $\delta[n+n_o] \leftrightarrow z^{no}$ 

If X(z) is rational, power series can be obtained by long division.

If X(z) is a rational function of z, i.e., a ratio of polynomials, we can also use partial fraction expansion to express X(z) as a sum of simple terms for which the inverse transform may be recognized by inspection. The ROC plays a critical role in this process.

#### • Consider the z-transform:

$$X(z) = \frac{3 - \frac{5}{6}z^{-1}}{\left(1 - \frac{1}{4}z^{-1}\right)\left(1 - \frac{1}{3}z^{-1}\right)}, |z| > \frac{1}{3}$$

• Consider the signal:

$$X(z) = 4z^{2} + 2 + 3z^{-1}, 0 < |z| < \infty$$

# Analysis & Characterization of LTI Systems

#### LTI Systems Using z-Transforms

- The z-transform plays a particularly important role in the analysis and representation of discrete time LTI system.
- From the convolution property: Y(z) = H(z) X(z).
- Where X(z), Y(z) and H(z) are the z-transforms of the system input, output and impulse response respectively.
- H(z) is referred to as the system function or transfer function of the system.
- For z-evaluated on the unit circle (i.e., z = e<sup>jω</sup>), H(z) reduces to the frequency response of the system, provided that the unit circle is in the ROC for H(z).
- We know that if the input to an LTI system is the complex exponential x[n] = z<sup>n</sup>, then the output will be H(z) z<sup>n</sup>.
- That is z<sup>n</sup> is an Eigen-function of the system with eigenvalue given by H(z), the z-transform of the impulse response.

#### LTI Systems Using z-Transforms (cont.)

 Many properties of a system can be tied directly to characteristics of the poles, zeros, and region of convergence of the system function.

 Lets discuss few of the system properties of ztransform, that is:

- Causality
- Stability

#### Causality

- A discrete-time LTI system is causal if and only if ROC is the exterior of a circle (including ∞).
- Proof:
- A system is causal if and only if: h[n] = 0, n<0.</li>
  Therefore, h[n] must be right sided. Property 5 implies that ROC is outside a circle.

• Also, by the definition that:

$$H(z) = \sum_{n=0}^{\infty} h[n] z^{-n}$$

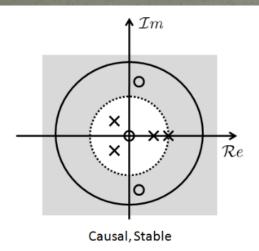

Where there is no positive powers of z, H(z) converges also when z→∞.

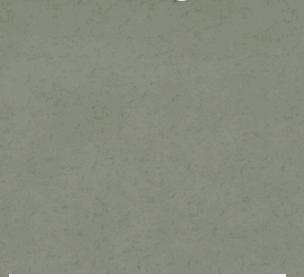

• |z| > 1 when  $z \rightarrow \infty$ .

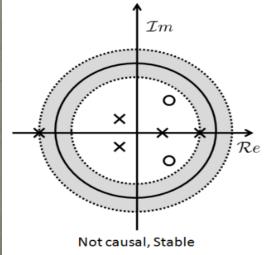

#### Stability

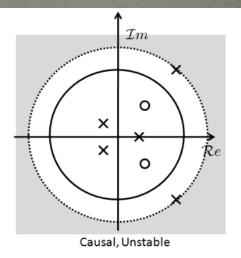

- A discrete time LTI system is stable if and only if ROC of H(z) includes the unit circle.
- Proof: A system is stable if and only if h[n] is absolutely summable, if and only if DTFT of h[n] exists. Consequently by property 2, ROC of H(z) must include the unit circle.
- A causal discrete-time LTI system is stable if and only if all of its poles are inside the unit circle.

## Examples

• Consider a system with system function:

$$H(z) = \frac{1}{1 - \frac{1}{2}z^{-1}} + \frac{1}{1 - 2z^{-1}}, |z| > 2$$

Whether the system is Causal or not?
Find h[n]=?

#### LTI Systems Characterized by LCCDE

 For systems characterized by liner constantcoefficient difference equations, the properties of the z-transform provide a particularly convenient procedure for obtaining the system function, function response or time domain response of the system.

 Consider an LTI system for which the input x[n] and the output y[n] satisfy the linear constant coefficient difference equation:

$$y[n] - \frac{1}{2}y[n-1] = x[n] + \frac{1}{3}x[n-1]$$

#### System Functions for Interconnections of LTI Systems

• The system function for the cascade of two discrete-time LTI systems is the product of the system functions for the individual systems in the cascade.

• Feedback interconnection of two systems is shown below:

• It is involved to determine the difference equation or impulse response for the overall system working directly in the time domain.

 However with the systems and sequences expressed in terms of their z-transforms, the analysis involves only algebraic equations.

System Functions for Interconnections  
of LTI Systems (cont.)  
$$Y(z) = Y_1(z) = X_2(z)$$
$$X_1(z) = X(z) - Y_2(z) = X(z) - H_2(z)Y(z)$$
$$Y(z) = H_1(z)X_1(z) = H_1(z)[X(z) - H_2(z)Y(z)]$$
$$\frac{Y(z)}{X(z)} = H(z) = \frac{H_1(z)}{1 + H_2(z)H_1(z)}$$

• ROC is determined based on roots of  $1+H_2(z)H_1(z)$ .

#### Block Diagram Representation for Causal LTI System

 Causal LTI systems can be described by difference equations using block diagram involving three basic operations:

- Addition
- Multiplication by a coefficient
- A unit delay

• Consider the causal LTI system with system function:

$$H(z) = \frac{1 - 2z^{-1}}{1 - \frac{1}{4}z^{-1}} = \left(\frac{1}{1 - \frac{1}{4}z^{-1}}\right) \left(1 - 2z^{-1}\right)$$

## The End
